

During the recreation where I mostly tackled the debugging process, the most difficult part for me was understanding how each part of the system connected with one another, especially in the backend. I constantly had to adjust and change the logic so the frontend, backend, and SQL database could connect properly with each other. A lot of the problems I encountered were caused by small errors in the connections between these three parts, which sometimes caused the system to crash or not function correctly. Because of this, debugging became the biggest challenge throughout the development process since I had to repeatedly test, trace errors, and figure out where the connection was failing.

Another challenge I experienced was making sure that every part of the system still worked correctly after making changes. Even small edits in the backend could affect the frontend or the SQL database. This made the process difficult because I had to carefully check everything whenever I changed something in the system.

If I were given more time, I would improve the module by removing unnecessary or redundant elements because there were still many parts that could be simplified. Doing this would make the system cleaner, easier to manage, and more efficient overall. I would also spend more time improving the frontend design by adding better styling and making the interface more user-friendly and visually appealing. I believe these improvements would make the module look more polished and complete.
