Individual Reflection

What was the most difficult part of interpreting the original author's logic?

The most difficult part for me was understanding how the system should work based only on the ERD and introduction of the original study. Since we did not have access to the actual original system, source code, or full implementation, we had to interpret how the module should function by analyzing the database structure and the descriptions provided in the documentation.

I found it challenging to understand how the tables were connected and how the patient records should flow within the system. Because of my limited experience in web development and databases, it took time for me to understand the relationships between the data and how CRUD operations should be implemented properly.

What technical challenges did you face during recreation?

One of the biggest challenges I faced was working with SQL and connecting the database to the system because I am still not very confident with backend development. I struggled with creating SQL queries, connecting PHP to MySQL, and understanding how the database interacts with the system.

There were times when the data would not display correctly or would not save because of errors in the queries or database connection. Another challenge was recreating the module without seeing the original working system. Since we only based our work on the ERD and introduction, we had to imagine how the features and interface should function. Because of this, there were times when I was unsure if my implementation matched the intended flow of the original project.

How would you improve this module further?

If I had more time and experience, I would improve the module by creating a more modern and organized design. I would like to improve the interface by making it cleaner, more responsive, and easier to navigate for users.

I would also add more features such as appointment scheduling, medical history tracking, better search and filtering options, and user authentication for added security. These features would make the system more realistic and more useful for an actual medical and dental clinic.
